Upper extremity dislocations are relatively common on account of the great range of motion the upper limb is capable of (a general principle is that the greater the range of motion of a joint, the more prone it is to dislocation). In many instances dislocations are associated with fractures either at the same joint (e.g. glenoid fractures in the setting of shoulder dislocation) or remote to ...

In the past 10 years, there has been a considerable shift in thinking about upper and lower extremity tendino-pathies, previously considered to result from cellular or biochemical inflammation. Recent literature has revealed consistent changes occurring in the most c-common tendinopathies'neurovascular ingrowth, variable tenocyte density (hyper- and hypocellularity), and abnormal or degenerate extracellular matrix.

Previous studies comparing upper and lower extremity recovery have evaluated disability rather than motor impairment. Individuals with lower extremity impairments may be more functional and appear less disabled than individuals with upper extremity impairments. Function of the upper extremity requires finer motor control, for which the patient can less readily compensate. Therefore, impairments and disability would predictably be more highly correlated in this area.

Blood pressure (BP) monitoring can be obtained non-invasively (NIBP) by oscillometry or invasively (IBP) by an arterial cannula. Limited data exists comparing NIBP to IBP and NBIP taken in the upper versus lower extremities in pediatric patients. With BP guiding major therapeutic decisions in pediatric intensive care units, inaccuracies may complicate the timely diagnosis and treatment of ...
